Lab 01 — How It Fits Together

What happens when your portal sends a reminder.

Two Ways to Perform the Same Action

- **The button:** you click **Send Reminder**, and your portal's code sends the request straight to the workshop server.
- **The chat window:** you type a request in plain English. The small Qwen model on the laptop turns it into a fixed format, such as the action, the internship and the date, and your portal's code checks it before sending anything. The model runs on the laptop, so what you type doesn't go to the cloud.
- **Either way, the same path out:** your portal's code sends the request over the internet, with the access key, to the workshop MCP server. Its `send_reminder` tool emails your table's lab account, which forwards it to the table leader's inbox.

Where's Claude?

Claude built your portal, but it isn't in this loop. Once it's built, your portal does the acting. That's the difference between a tool that helps you build something and the thing you built doing work on its own.
